

Abstract

The present invention relates to a method for determining a subject having a risk of having developed or developing prostate cancer, which comprises the following steps:

- 5 a) a step of analyzing the presence/absence or level of mutation in the PCA-1 gene derived from the subject; and
- b) a step of evaluating the presence/absence or level of the subject's risk of having developed or developing prostate cancer, based on the presence/absence or level of mutation in
- 10 the PCA-1 gene. According to the determination method of prostate cancer of the present invention, a subject having a risk of having developed or developing prostate cancer can be determined conveniently and highly sensitively. Therefore, the method is effective for the diagnosis of prostate cancer,
- 15 progress monitoring, prognostic prediction, diagnosis before the onset, carrier diagnosis and the like.
